Review: malloc()

- Mapping memory: `mmap()`, `munmap()`. Useful for demand paging.
- Resizing heap: `sbrk()`
- Designing `malloc()`
  - implicit linked list,explicit linked list
  - best fit,first fit,next fit
- Problems:
  - fragmentation
  - memory leaks
  - valgrind –tool=memcheck, checks for memory leaks.

- C does not have any garbage collectors
- Implementations available
- Types:
  - Mark and sweep garbage collector (depth first search)
  - Cheney's algorithm (breadth first search)
  - Copying garbage collector

Preliminaries: Parallel computing

- Parallelism: Multiple computations are done simultaneously.
  - Instruction level (pipelining)
  - Data parallelism (SIMD)
  - Task parallelism (embarrassingly parallel)
- Concurrency: Multiple computations that **may** be done in parallel.
- Concurrency vs. Parallelism

Process vs. Threads

- Process: An instance of a program that is being executed in its **own** address space. In POSIX systems, each process maintains its own heap, stack, registers, file descriptors etc.
  Communication:
  - Shared memory
  - Network
  - Pipes, Queues
- Thread: A light weight process that shares its address space with others.In POSIX systems, each thread maintains the bare essentials: registers, stack, signals.
  Communication:
  - shared address space.

Multithreaded concurrency

Serial execution:

- All our programs so far has had a single thread of execution: main thread.
- Program exits when the main thread exits.

Multithreaded:

- Program is organized as multiple and concurrent threads of execution.
- The main thread *spawns* multiple threads.
- The thread **may** communicate with one another.
- Advantages:
  - Improves performance
  - Improves responsiveness
  - Improves utilization
  - less overhead compared to multiple processes

Multithreaded programming

Even in C, multithread programming may be accomplished in several ways

- Pthreads: POSIX C library.
- OpenMP
- Intel threading building blocks
- Cilk (from CSAIL!)
- Grand central despatch
- CUDA (GPU)
- OpenCL (GPU/CPU)

Not all code can be made parallel

```
float params[10];
for(int i=0;i<10;i++)
  do_something(params[i]);
```

paralleizable

```
float params[10];
float prev=0;
for(int i=0;i<10;i++)
{
  prev=complicated(params[i],prev);
}
```

not parallelizable

Not all multi-threaded code is safe

```
int balance=500;
void deposit(int sum){
  int currbalance=balance;/*read balance*/
  ...
  currbalance+=sum;
  balance=currbalance;/*write balance*/
}

void withdraw(int sum){
  int currbalance=balance;/*read balance*/
  if(currbalance>0)
    currbalance-=sum;
  balance=currbalance; /*write balance*/
}
  ..
  deposit(100);/*thread 1*/
  ..
  withdraw(50);/thread 2*/
  ..
  withdraw(100);/*thread 3*/
    ...
```

- minimize use of global/static memory
- Scenario: T1(read),T2(read,write),T1(write) ,balance=600
- Scenario: T2(read),T1(read,write),T2(write) ,balance=450

- Review
- Multithreaded programming
  - Concepts
- Pthread
  - API
  - Mutex
  - Condition variables

Pthread

API:

- Thread management: creating, joining, attributes

  pthread_

- Mutexes: create, destroy mutexes

  pthread_mutex_

- Condition variables: create,destroy,wait,signal

  pthread_cond_

- Synchronization: read/write locks and barriers

  pthread_rwlock_, pthread_barrier_

API:

- **#include** <pthread.h>
- gcc −Wall −O0 −o <output> file.c −pthread (no −l prefix)

Creating threads

```
int pthread_create(pthread_t * thread,
                   const pthread_attr_t * attr,
                   void *(*start_routine)(void*), void * arg);
```

- creates a new thread with the attributes specified by `attr`.
- Default attributes are used if `attr` is NULL.
- On success, stores the thread it into `thread`
- calls function `start_routine(arg)` on a separate thread of execution.
- returns zero on success, non-zero on error.

```
void pthread_exit(void *value_ptr);
```

- called implicitly when thread function exits.
- analogous to `exit()`.

Example

```
#include <pthread.h>
#include <stdio.h>
#define NUM_THREADS     5

void *PrintHello(void *threadid)
{
   long tid;
   tid = (long)threadid;
   printf("Hello World! It's me, thread #%ld!\n", tid);
   pthread_exit(NULL);
}

int main (int argc, char *argv[])
{
   pthread_t threads[NUM_THREADS];
   int rc;
   long t;
   for(t=0; t<NUM_THREADS; t++){
      printf("In main: creating thread %ld\n", t);
      rc = pthread_create(&threads[t], NULL, PrintHello, (void *)t);
      if (rc){
         printf("ERROR; return code from pthread_create() is %d\n", rc);
         exit(-1);
      }
   }
   pthread_exit(NULL);
}
```

code: https://computing.llnl.gov/tutorials/pthreads/

Output

```
In main: creating thread 0
In main: creating thread 1
Hello World! It's me, thread #0!
Hello World! It's me, thread #1!
In main: creating thread 2
In main: creating thread 3
Hello World! It's me, thread #2!
Hello World! It's me, thread #3!
In main: creating thread 4
Hello World! It's me, thread #4!
```

```
In main: creating thread 0
Hello World! It's me, thread #0!
In main: creating thread 1
Hello World! It's me, thread #1!
In main: creating thread 2
Hello World! It's me, thread #2!
In main: creating thread 3
Hello World! It's me, thread #3!
In main: creating thread 4
Hello World! It's me, thread #4!
```

Synchronization: joining

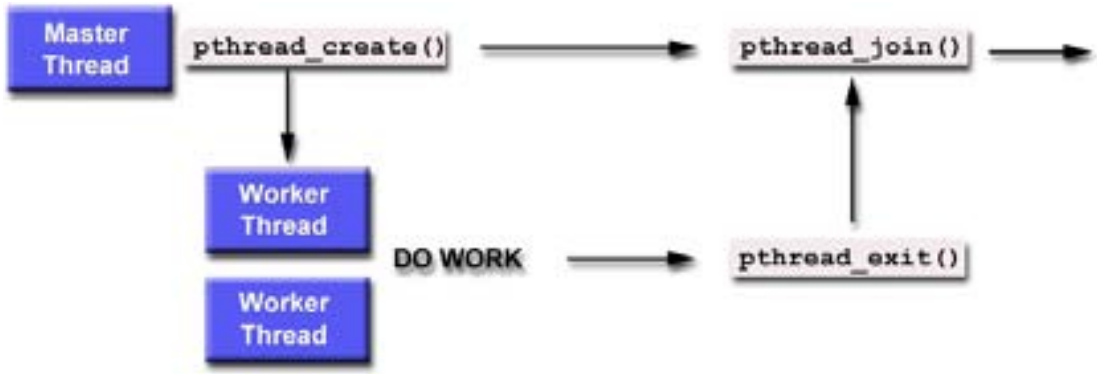

Figure: https://computing.llnl.gov/tutorials/pthreads

```
int pthread_join(pthread_t thread, void **value_ptr);
```

- pthread_join() blocks the calling thread until the specified thread terminates.
- If value_ptr is not null, it will contain the return status of the called thread

Other ways to synchronize: mutex,condition variables

Mutex

- Mutex (mutual exclusion) acts as a "lock" protecting access to the shared resource.
- Only one thread can "own" the mutex at a time. Threads must take turns to lock the mutex.

```
int pthread_mutex_destroy(pthread_mutex_t *mutex);
int pthread_mutex_init(pthread_mutex_t * mutex,
                const pthread_mutexattr_t * attr);
thread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;
```

- pthread_mutex_init() initializes a mutex. If attributes are NULL, default attributes are used.
- The macro PTHREAD_MUTEX_INITIALIZER can be used to initialize static mutexes.
- pthread_mutex_destroy() destroys the mutex.
- Both function return return 0 on success, non zero on error.

Mutex

```
int pthread_mutex_lock(pthread_mutex_t *mutex);
int pthread_mutex_trylock(pthread_mutex_t *mutex);
int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

- pthread_mutex_lock() locks the given mutex. If the mutex is locked, the function is blocked until it becomes available.
- pthread_mutex_trylock() is the non-blocking version. If the mutex is currently locked the call will return immediately.
- pthread_mutex_unlock() unlocks the mutex.

Example revisited

```
int balance=500;
void deposit(int sum){
  int currbalance=balance;/*read balance*/
  ...
  currbalance+=sum;
  balance=currbalance;/*write balance*/
}

void withdraw(int sum){
  int currbalance=balance;/*read balance*/
  if(currbalance>0)
    currbalance-=sum;
  balance=currbalance; /*write balance*/
}
  ..
  deposit(100);/*thread 1*/
  ..
  withdraw(50);/thread 2*/
  ..
  withdraw(100);/*thread 3*/
    ...
```

- Scenario: T1(read),T2(read,write),T1(write),balance=600
- Scenario: T2(read),T1(read,write),T2(write),balance=450

Using mutex

```
int balance=500;
pthread_mutex_t mutexbalance=PTHREAD_MUTEX_INITIALIZER;

void deposit(int sum){
  pthread_mutex_lock(&mutexbalance);
  {
  int currbalance=balance;/*read balance*/
  ...
  currbalance+=sum;
  balance=currbalance;/*write balance*/
  }
  pthread_mutex_unlock(&mutexbalance);
}
void withdraw(int sum){
  pthread_mutex_lock(&mutexbalance);
  {
  int currbalance=balance;/*read balance*/
  if(currbalance>0)
    currbalance-=sum;
  balance=currbalance; /*write balance*/
  }
  pthread_mutex_unlock(&mutexbalance);
}
..   deposit(100);/*thread 1*/
..   withdraw(50);/thread 2*/
..   withdraw(100);/*thread 3*/
```

- Scenario: T1(read,write),T2(read,write),balance=550
- Scenario: T2(read),T1(read,write),T2(write),balance=550

Condition variables

Sometimes locking or unlocking is based on a run-time condition (examples?).Without condition variables, program would have to poll the variable/condition continuously.
Consumer:

(a) lock mutex on global item variable

(b) wait for (item>0) signal from producer (mutex unlocked automatically).

(c) wake up when signalled (mutex locked again automatically), unlock mutex and proceed.

Producer:

(1) produce something

(2) Lock global item variable, update item

(3) signal waiting (threads)

(4) unlock mutex

Condition variables

```
int pthread_cond_destroy(pthread_cond_t *cond);
int pthread_cond_init(pthread_cond_t * cond,const pthread_condattr_t * attr);
pthread_cond_t cond = PTHREAD_COND_INITIALIZER;
```

- pthread_cond_init() initialized the condition variable. If attr is NULL, default attributes are sed.
- pthread_cond_destroy() will destroy (uninitialize) the condition variable.
- destroying a condition variable upon which other threads are currently blocked results in undefined behavior.
- macro PTHREAD_COND_INITIALIZER can be used to initialize condition variables. No error checks are performed.
- Both function return 0 on success and non-zero otherwise.

Condition variables

```
int pthread_cond_destroy(pthread_cond_t *cond);
int pthread_cond_init(pthread_cond_t * cond,const pthread_condattr_t * attr);
pthread_cond_t cond = PTHREAD_COND_INITIALIZER;
```

- pthread_cond_init() initialized the condition variable. If attr is NULL, default attributes are sed.
- pthread_cond_destroy() will destroy (uninitialize) the condition variable.
- destroying a condition variable upon which other threads are currently blocked results in undefined behavior.
- macro PTHREAD_COND_INITIALIZER can be used to initialize condition variables. No error checks are performed.
- Both function return 0 on success and non-zero otherwise.

Condition variables

```
int pthread_cond_wait(pthread_cond_t *cond,pthread_mutex_t *mutex);
```

- blocks on a condition variable.
- must be called with the mutex already locked otherwise behavior undefined.
- automatically releases mutex
- upon successful return, the mutex will be automatically locked again.

```
int pthread_cond_broadcast(pthread_cond_t *cond);
```

```
int pthread_cond_signal(pthread_cond_t *cond);
```

- unblocks threads waiting on a condition variable.
- `pthread_cond_broadcast()` unlocks **all** threads that are waiting.
- `pthread_cond_signal()` unlocks **one of** the threads that are waiting.
- both return 0 on success, non zero otherwise.

Example

```
#include<pthread.h>
pthread_cond_t   cond_recv=PTHREAD_COND_INITIALIZER;
pthread_cond_t   cond_send=PTHREAD_COND_INITIALIZER;
pthread_mutex_t  cond_mutex=PTHREAD_MUTEX_INITIALIZER;
pthread_mutex_t  count_mutex=PTHREAD_MUTEX_INITIALIZER;

int  full=0;
int  count=0;
```

```
void* produce(void*)
{
  while(1)
  {
      pthread_mutex_lock(&cond_mutex);
    while(full)
  {
    pthread_cond_wait(&cond_recv,
                &cond_mutex);
  }
      pthread_mutex_unlock(&cond_mutex);
      pthread_mutex_lock(&count_mutex);
      count++;full=1;
      printf("produced(%d):%d\n",
      pthread_self(),count);
      pthread_cond_broadcast(&cond_send);
      pthread_mutex_unlock(&count_mutex);
      if(count>=10)  break;
    }
```

```
void* consume(void*)
{
  while(1)
    {
      pthread_mutex_lock(&cond_mutex);
      while(!full)
  {
    pthread_cond_wait(&cond_send,
    &cond_mutex);
  }
      pthread_mutex_unlock(&cond_mutex);
      pthread_mutex_lock(&count_mutex);
      full=0;
      printf("consumed(%ld):%d\n",
      pthread_self(),count);
      pthread_cond_broadcast(&cond_recv);
      pthread_mutex_unlock(&count_mutex);
      if(count>=10)break;
    }
```

Example

```
int main()
{
   pthread_t cons_thread,prod_thread;
   pthread_create(&prod_thread,NULL,produce,NULL);
   pthread_create(&cons_thread,NULL,consume,NULL);

   pthread_join(cons_thread,NULL);
   pthread_join(prod_thread,NULL);
   return 0;
}
```

Output:

```
produced(3077516144):1
consumed(3069123440):1
produced(3077516144):2
consumed(3069123440):2
produced(3077516144):3
consumed(3069123440):3
produced(3077516144):4
consumed(3069123440):4
produced(3077516144):5
consumed(3069123440):5
produced(3077516144):6
consumed(3069123440):6
produced(3077516144):7
consumed(3069123440):7
```

Summary

- Parallel programming concepts
- Multithreaded programming
- Pthreads
- Syncrhonization
- Mutex
- Condition variables
